Technical possibilities for coronary artery bypass surgery and the outlook for graft patency

Summary

In an attempt to analyse the results of saphenous bypass grafting, 213 patients were re-investigated by repeat coronary, graft and left ventricular angiography. In this series, the presence of diffuse arterial disease was not considered as a contra-indication to operation. Instead, additional endarterectomy was performed.

The overall patency rate was 88% and was not significantly altered by the passage of time, although the patency rate during the first 6 months was 94%. The patency rate did not appear to be influenced by the age of the patient, the severity of the lesion pre-operatively, the artery grafted nor additional endarterectomy. The run-off was judged to be good in 82% of grafts investigated before 6 months, compared to 70% of those investigated later. Progress of the disease in the native vessels appeared to be slightly accelerated in the segment proximal to the graft.

Introduction

Although myocardial revascularization by saphenous or internal mammary bypass grafting is now established, we believe that at this stage of our knowledge it is essential to continue to evaluate critically the results of these procedures.

The early and long-term results of the operation should depend upon the ability of the inserted grafts to remain patent, and on the changes in the native coronary circulation following grafting. It has been our policy not to regard the presence of diffuse arterial disease nor the angiographic non-visualization of the distal segment beyond the obstruction as contra-indications to operation. In these patients, the vessel is examined at the time of operation and additional endarterectomy is performed if necessary.

The purpose of this paper is to analyse the results of this policy and to attempt to define the early and late behaviour of the grafts and their effect on the native coronary circulation.

Patients and methods

Two hundred and thirteen patients, who underwent coronary grafts, were re-investigated by repeat coronary, graft and left ventricular angiography. The indication for this was routine re-investigation or recurrence of symptoms. Two hundred and three were male and ten female, with ages varying between 27 and 68 years. The period between operation and investigation varied from 2 weeks to 48 months (mean 20 months). For the sake of analysis, grafts which could not be entered were considered occluded. The run-off was graded into good, moderate or poor by two independent observers. The operative technique, with or without endarterectomy, has been described elsewhere (Yacoub et al., 1974, 1975).

Results

Of the 441 grafts investigated, 388 were shown to be patent, representing an overall patency rate of 88% (Fig. 1). The patency rate of grafts investigated during the first 6 months was 94%, compared to 83% for those investigated 1–4 years after operation (Fig. 1). This difference, however, did not reach statistical significance. Of the patients investigated, 95% had one or more patent graft (Fig. 2). This was not significantly altered with the age of the patient (Fig. 3) nor the time between operation and investigation (Fig. 2). The patency rate of grafts to different arteries was remarkably similar (Fig. 4). The number of inserted grafts in each patient did not affect the patency rate (Fig. 5). However, as can be expected, 93% of patients with a single graft had one graft patent compared to 100% of those with three or more grafts.

Additional endarterectomy (using carbon dioxide in most cases) did not affect the patency rate. Thus, out of eighty-six grafts to endarterectomized arteries seventy-six were patent, representing a patency rate of 88% which was identical to the patency rate of the 355 grafts to non-endarterectomized arteries (Fig. 6).
Coronary artery bypass and graft patency

There was no significant change in patency rate of grafts to endarterectomized arteries with the passage of time (Fig. 7). The run-off of grafts to endarterectomized arteries was judged to be good in 73% of cases, compared to 76% for non-endarterectomized arteries (Fig. 8). The patency rate, as well as the run-off of grafts to endarterectomized arteries was similar for the right and left coronary systems (Fig. 9).

The effect of the pre-operative degree of stenosis of the grafted vessel on the patency rate was examined by analysing the patency rate of the grafts to the arteries which were totally occluded before opera-

![Fig. 9. Run-off in patent grafts to endarterectomized arteries. □, Occluded; ■, moderate; □, poor; □, good. RC, right coronary; LAD, left anterior descending; Cx, circumflex.](image)

![Fig. 10. Patency rate in 108 grafts to vessels totally occluded before operation. □, Patent; ■, occluded. RC, right coronary; LAD, left anterior descending; Cx, circumflex.](image)

![Fig. 11. Effect of grafting on native coronary circulation. Follow-up 6-48 months (mean 20 months), eighty-six patients. N, non-grafted vessel; G, grafted vessel. □, Progress of disease; □, disease static.](image)
of the coronary vessels distal to the anastomosis (the run-off) was analysed in relation to time (Fig. 12). This showed 82% of the run-off grafts investigated early (before 6 months) were judged to be good, compared to 70% of those investigated late. This difference, however, is not statistically significant.

Discussion
The present study has shown that saphenous vein bypass grafts continue to function satisfactorily for a period of up to 4 years. The patency rate does not appear to be influenced by the age or the sex of the patient, the artery grafted, the severity of the lesion pre-operatively, additional endarterectomy nor the interval between operation and re-investigation. Progress of the disease appeared to be slightly accelerated in the segment proximal to a patent graft. Further studies are required to define the long-term results of the operation.
