Summary
The test for exocrine pancreatic function using N-benzoyl-L-tyrosyl-p-aminobenzoic acid (BTPABA test) was assessed in 7 patients with giardiasis and 7 healthy controls. Cumulative percent p-aminobenzoic acid (PABA) recovery in 6 hr was significantly lower in patients with giardiasis, compared with the control group. When an equivalent dose of free PABA was given, there were no differences in PABA recovery between the groups. In patients with giardiasis, the post-treatment values of BTPABA test were significantly higher than the pretreatment values and no differences were found in PABA recovery between patients with giardiasis after eradication and healthy controls. These findings indicate that Giardia lamblia interferes with the action of pancreatic chymotrypsin. It is noteworthy that giardiasis could cause an abnormal BTPABA test.

KEY WORDS: pancreatic function, BTPABA, giardiasis.

Introduction
Although giardiasis as a cause of diarrhoea, malabsorption and biliary tract dysfunction (Petersen, 1972; Ericraizman, 1976; Goldstein, Thornton and Szydrowski, 1978; Jahadi, 1978) has been increasingly recognized in the world, little attention has been paid to the assessment of exocrine pancreatic function in patients with giardiasis. The present study reports that Giardia lamblia interferes with the action of pancreatic chymotrypsin.

Patients
Fourteen subjects were studied, 7 controls and 7 patients.

Controls
There were 5 men and 2 women healthy volunteers, aged 21–78 years (mean 49·1). In none was there clinical or laboratory evidence of gastrointestinal, hepatobiliary, pancreatic, or renal disease. There was no history of alcoholism.

Patients
Seven consecutive patients with giardiasis, 6 men and one woman, admitted to our clinic during the period from October 1979 to December 1981, were studied. The ages ranged from 27 to 59 years (mean 39·7). The diagnosis of giardiasis was confirmed by both stool examination and microscopic examination of the duodenal aspirate. Of these, 5 patients had symptoms such as upper abdominal pain, low grade fever, general malaise, and soft stool. The remaining two patients were asymptomatic; one admitted for acromegaly, the other for a check-up. All patients had normal renal and liver function values and normal findings on oral cholecystography, barium meal and small intestinal X-rays. In no patient was there a history of alcoholism.

Methods
The following were performed to all subjects:
(1) N-benzoyl-L-tyrosyl-p-aminobenzoic acid (BTPABA) test. After an overnight fast, urine was
collected before, and for 6 hr after, the oral administration of 0·5 g BTPABA containing 169·5 mg of p-aminobenzoic acid (PABA); (2) free PABA test. Within 4 days after the BTPABA test, a similar procedure was carried out except that the peptide dose was replaced by an equimolar dose (169·5 mg) of free PABA (Eizai Co., Tokyo, Japan).

The concentration of aromatic amines in urine was determined by the method of Bratton and Marshall (1939), as modified by Smith et al. (1945). Total recovery of PABA in the 6 hr urine samples was expressed as a percentage of the oral dose given as follows:

\[
\% \text{ recovery} = \frac{\text{total aromatic amines (mg)}}{169.5 \text{ mg of PABA}} \times 100.
\]

In patients with giardiasis, metronidazole 250 mg thrice daily for 10 days was used to eradicate the parasite. Eradication was confirmed by both stool examination and microscopic examination of duodenal aspirates. At least a fortnight after proven eradication, the above tests were repeated.

For comparison of results in different groups, Student's \( t \)-test was used. Paired \( t \)-test was used for paired data samples.

Results

The results of the BTPABA test are shown in Fig. 1 as the recovery rate of PABA in the urine per 6 hr. Values of the control group averaged 81·3 ± 8·4% (mean ± 1 s.d.) compared with 64·4 ± 6·8% in giardiasis. A complete separation was obtained between the two groups. The difference in the values of the two groups was highly significant (\( P < 0.005 \)).

The results of the free PABA test are shown in Fig. 2. Values in the control group were 86·9 ± 5·9% compared with 84·3 ± 5·3% in giardiasis, a difference that was not statistically significant.

In patients with giardiasis, the results of the BTPABA test were compared before and after eradication (Fig. 3). The recovery rate of PABA was significantly higher after treatment (\( P < 0.001 \)). With therapy, the symptoms disappeared in 5 patients who had symptoms before treatment. There were no significant differences between patients with giardiasis after eradication and the controls.

Discussion

*Giardia lamblia* is an inhabitant of the upper gastrointestinal tract close to the opening of the pancreatic duct. Thus, it was proposed that the protozoon caused pancreatic insufficiency by invading the pancreatic duct (DeMuro, 1939). However, little information is available in the literature regard-
BTPABA test in giardiasis

**FIG. 3. BTPABA test.** Cumulative 6 hr PABA recovery before and after treatment of giardiasis. There is a significant rise in the PABA recovery after treatment ($P<0.001$).

In our study, the recovery rate of PABA in the BTPABA test was significantly lower in patients with giardiasis than in the controls, though in the free PABA test no differences were found between the groups. Moreover, in patients with giardiasis, the post-treatment values in the BTPABA test were significantly higher than the pretreatment values. These findings indicate that *Giardia lamblia* interferes with the action of pancreatic chymotrypsin.

Although its exact cause is unclear, there seem to be several possible mechanisms—direct pancreatic parenchymal damage, mechanical blockage of pancreatic duct, interference with the activating system of pancreatic enzymes in the duodenum and production of inhibitor of pancreatic enzymes, and bacterial overgrowth interfering with chymotrypsin activation.
