Summary: A 64 year old woman with metastatic endometrial carcinoma was admitted to the hospital after three grand mal seizures. Blood cultures yielded Corynebacterium striatum. The patient responded to parenteral ampicillin therapy. This is believed to be the first case of sepsis caused by this organism.

Introduction

Neutropenic patients are susceptible to a wide variety of infections from unusual organisms. The incidence of bacteraemia increases as the neutrophil count falls below $500 \times 10^9/l$ with most of the organisms originating from the patient’s endogenous flora. The organism implicated in this case, Corynebacterium striatum, is recognized as a part of the microbial flora of the human skin and nasal mucous membranes.

We believe this report to be the first documented case of sepsis caused by C. striatum.

Case report

A 64 year old woman was admitted to the hospital after three grand mal seizures. She was known to have metastatic endometrial carcinoma diagnosed initially in 1985, treated with radiation therapy in 1985. Four months prior to admission, metastatic lesions were noted in lymph nodes, lung and brain. A Hickman catheter was inserted by the subclavian route and chemotherapy was begun with cis-platinum, cyclophosphamide, and doxorubicin. She received her last dose of chemotherapy 11 days before admission. The patient was diabetic and hypertensive requiring chronic insulin and diuretic therapy. Physical examination revealed a patient in no acute distress with a temperature of 102.3°F, blood pressure of 110/60 mmHg and pulse 100/minute. Her neck was supple, examination of the lungs revealed decreased breath sounds bilaterally, abdominal examination revealed a 16 cm hard nodular liver, and rectal examination was positive for occult blood. Initial laboratory results included: haemoglobin 7.8 g/dl, platelet count 95 x 10^9/l, and white blood cell count 0.99 x 10^9/l (48% polymorphonuclear leucocytes). Chest X-ray, and cranial computed tomography revealed multiple metastatic lesions. Two sets of blood cultures (4/4 bottles) obtained on admission revealed a nonsporulating, aerobic, weakly haemolytic, nonmotile, catalase positive, pleomorphic diptheroid-like, Gram-positive bacillus which fermented glucose, fructose, mannose, lactose and maltose. The identification of the isolate was confirmed by the Missouri State Laboratory as Corynebacterium striatum. Minimal antibiotic inhibitory concentrations of the isolate included: ampicillin < 0.25 µg/ml, cephalothin < 4 µg/ml, chloramphenicol < 2 µg/ml, clindamycin < 0.5 µg/ml, erythromycin < 0.5 µg/ml, gentamicin < 1 µg/ml, oxacillin 0.5 µg/ml, penicillin 0.6 µg/ml, and vancomycin < 2 µg/ml.

Therapy was initiated with ampicillin 1 gram intravenously every 4 hours and gentamicin 120 mg every 8 hours, on the first day of hospitalization. Four days after antibiotics were started, the patient became afebrile, white blood cell count rose to 2.3 x 10^9/l and repeat blood cultures were sterile. Parenteral therapy was discontinued after 7 days and she was continued on ampicillin 500 mg orally every 6 hours for 7 additional days.

Discussion

Corynebacterium species, other than diphtheriae, that have caused bacteraemia include C. xerosis,1,2 C. pseudodiphtheriticum,3 C. equi,4 C. bovis,5,6 C. haemolyticum,7 C. aquaticum,8 C. (Actinomyces) pyogenes,9,10 C. group JK,4,7,11 and C. group G-212. This organism was first isolated from human nasal mucosa and named Bacterium striatum by Chester13; however,
Holland, classified the organism later as *C. flavidum*. *C. striatum* has only been reported twice as a human pathogen, once as a cause of pleuropulmonary infection in a patient with chronic lymphocytic leukaemia and once from a patient with a pulmonary abscess and empyema.

Species of *Corynebacterium* (diptheroids) are normally present on the skin and mucous membranes in large numbers. While usually considered a contaminant in the normal host, identification of the organisms in the neutropenic patient often represents severe infection. We describe in a granulocytopenic patient the first reported case of *Corynebacterium striatum* septicaemia.
