Summary: This is a case report of a 67 year old man who presented with a fluctuating level of consciousness and myoclonic jerks caused in part by hypercalcaemia. The diagnosis of cerebral neoplastic angioendotheliosis was only made later on brain biopsy and is the first report of the occurrence of hypercalcaemia in neoplastic angioendotheliosis.

Introduction

The condition known as neoplastic angioendotheliosis was first described in 1959 by Pfleger and Tappeiner.¹ The disease usually presents with a nonspecific encephalopathic illness or with skin involvement² without gross metabolic disturbances. We report a patient in whom a typical neurological illness was complicated by hypercalcaemia.

Case report

A 67 year old man presented to another hospital with a 4-week history of pain in his legs, difficulty in passing urine and an unsteady gait. Sensory loss was noted over the L5 to S2 dermatomes on his left leg and mild intellectual deterioration was suspected. All biochemical investigations were normal at this stage.

Three months later he developed urinary retention and the intellectual deterioration was marked. On examination he now looked parkinsonian, had bilateral grasp reflexes and extensor plantars but had no focal neurological signs. Subsequently his consciousness level began to fluctuate and he developed generalized multifocal myoclonus.

On admission to the National Hospitals he was unconscious, responding only to pain; generalized myoclonic jerks were noted. He had quadriiceps muscle wasting but knee and ankle reflexes were preserved. Other neurological signs were unchanged.

After initial investigations had shown hypercalcaemia he was treated with forced diuresis and corticosteroids. The myoclonus resolved and there was partial improvement in his conscious level up to the point of understanding simple commands. However, he remained mostly disoriented with periods of agitation and paranoia. Some seizures occurred, usually with a focal onset in the right arm and distinguished by headturning to the right.

Investigations to date had not reached a diagnosis so a right frontal brain biopsy was performed. Histology diagnosed angioendotheliosis and the patient was transferred for radiotherapy and chemotherapy. His condition deteriorated and he died after only one session of radiotherapy had been completed.

Investigations

There was a mild normocytic normochromic anaemia (haemoglobin 11.3 g/dl), and a raised ESR (30–59 mm/h). Bone marrow examination was normal. Cerebrospinal fluid (CSF) proteinosis was noted (140 g/dl) and there was a slight lymphocytosis (5 × 10⁹/l).

On admission there was marked hypercalcaemia (corrected for albumin of 3.73 mmol/l; albumin 31 g/l), low inorganic phosphate (0.70 mmol/l), hypernatraemia (158 mmol/l), hypokalaemia (2.10 mmol/l) and a slightly raised blood urea (10 mmol/l).

After treatment and rehydration, the electrolytes returned to normal over 8 days. The hypercalcaemia alone recurred after 14 days suggesting other causes besides dehydration were involved. Urinary calcium (5.3 mmol/l), inorganic phosphate (14 mmol/l) and the calcium:creatinine ratio were normal (0.023).
Further investigations excluded paraproteinaemia and systemic or meningeal sarcoidosis [CSF angiotensin converting enzyme (ACE) <2 kU/l; serum 28 kU/l. Reference limits <4, <45 kU/l, respectively]. Serum cortisol levels (310 mmol/l), n- and c-terminal parathyroid hormone (PTH) (<40 pg/l) were normal and 25-hydroxycholecalciferol levels (25-HCC) (14 ng/l) were borderline low (reference limits 14–30 ng/l). However, serum alkaline phosphatase was raised at 359 kU/l with a raised bone isoform fraction (120 U/ml; limit 75 U/ml) and normal liver isoform fraction (50 U/ml; limit 55 U/ml) in the absence of other hepatic function derangements. The alkaline phosphatase was principally the bone isoform (270 kU/l).

Serology, including human T cell leukaemia virus type 1 (HTLV1) and human immunodeficiency virus (HIV) titres, was unremarkable.

Skeletal radiology and bone scintigraphy were normal. Computed tomographic and magnetic resonance imaging scans showed generalized cerebral atrophy representative of small vessel disease.

Histopathology: the full thickness cerebral and meningeal biopsy was stained with haematoxylin and eosin (H&E), haematoxylin-van Gieson, reticulin and immunocytochemical stains. Many of the smaller cortical blood vessels and some meningeal vessels were filled with abnormal large bizarre malignant leucocytes (Figure 1). Immunocytochemical stains (leucocyte common antigen – LCA, and a T&B cell marker panel) showed that these cells were positive for B cell markers (immunglobulin, CD25, UCH L-26), weakly reactive for LCA but not for T cell or epithelial markers (Figure 2). Morphological appearances were consistent with neoplastic angioendotheliosis of an immunological B cell phenotype. After death, a necropsy was not performed.

Discussion

Neoplastic angioendotheliosis (NAE) is a rare tumour affecting ectodermal tissues whose cell of origin is disputed. Recent evidence has favoured a lymphomatous origin over an endothelial one. Metabolic abnormalities are rare having only been seen in a case of protein losing enteropathy associated with B-cell NAE.

The patient presented principally with a fluctuating encephalopathy due probably to central NAE, compounded by hypercalcaemia but with features of cauda equina and spinal cord involvement. The previously unsuspected diagnosis was only finally made on brain biopsy. The malignant cells were immunologically of B cell phenotype. Hypercalcaemia occurs in 1.8–3% of lymphomas especially those of large cell morphology or associated with human T cell leukaemia virus type 1 (HTLV1) infection.

The mechanism of hypercalcaemia remains obscure but abnormal hydroxycholecalciferol metabolism, lymphokines, prostaglandins and a tumour PTH-like factor are known to be involved. This patient had a low serum PTH activity, normal 25-HCC, low phosphate and raised bone alkaline phosphatase, implying a role for PTH-like factors. However, it was not possible to measure urinary cyclic AMP levels. There is no current assay for tumour PTH and it does not immunologically

Figure 1  Intravascular neoplastic cells. The large nuclei with abundant chromatin, prominent multiple nucleoli and scant cytoplasm are characteristic of lymphoma. Note the single intravascular mitotic figure in the centre of the field. H&E, scale bar = 50 μm.
The immunocytochemistry in this case strengthens the evidence that NAE is a form of lymphoid neoplasia and should be called 'intravascular lymphomatosis'. The biochemical findings in this case show that, like other lymphomas, it can be complicated by significant hypercalcaemia.

Acknowledgements

We would like to thank Dr C.H. Hawkes for referring the case, Mr N. Grant for performing the brain biopsy, Professor P.G. Isaacson for the monoclonal antibody UCH L-26 and Mrs P. Jaeger and Ms H. Ayling for preparing the microscope slides.
