

In view of the atypical presentation a fungal culture was done from the last CSF sample. From this, a pure growth of *Nocardia brasiliensis* was obtained after 2 weeks of incubation on Sabouraud’s dextrose agar. This was identified by the standard methods.¹ The sulphonamides group of drugs are more frequently used in treatment of nocardiosis. Hence we chose to use a high dose co-trimoxazole infusion in a dose of 20 mg/kg of trimethoprim. She improved in 48 hours and this improvement persisted. We were able to change over after a week to an oral regime of the drug at the same high dose.

*Nocardia brasiliensis* is widespread in soil samples.² Infections present predominantly as cutaneous or subcutaneous infections as mycetoma and lymphocutaneous diseases.³ Systemic and disseminated forms of infection have been sporadically reported.¹³ Pulmonary involvement is the commonest systemic manifestation. Involvement of the central nervous system mainly as a meningitis has to the best of our knowledge not been previously reported. This case also emphasizes the usefulness of a high dose of co-trimoxazole therapy for *N. brasiliensis* infections.

**Nocardia brasiliensis meningitis**

Sir,

A 23 year old female agricultural worker presented with progressive visual loss of 6 months duration and intermittent mild headache of 2 months. On examination there was a marked reduction in visual acuity in both eyes with a 2/60 vision. Ophthalmoscopy showed changes consistent with a primary optic atrophy. There were no meningeal signs or other significant findings on systemic examination. Routine screening tests were normal and VDRL was negative. A lumbar puncture was done which showed a normal cerebrospinal fluid (CSF).

A provisional diagnosis of a demyelinating disorder was made and prednisolone was started at a dose of 40 mg per day. Six days later she developed a high grade fever with severe headache and vomiting. There were no meningeal signs and the sensorium was not clouded. A repeat lumbar puncture showed a cell count of 2,000/mm³ consisting of predominantly lymphocytes and a moderately low CSF sugar. The possibility of a viral meningitis was considered and the steroids were tapered off. However, 2 days later she developed meningeal signs and we opted to use a combination of intravenous penicillin, chloramphenicol and gentamicin though bacterial cultures remained sterile. Within 48 hours of starting these drugs there was considerable improvement in her clinical signs but in another 5 days they all recurred. At this stage computed tomography head scan was done which was normal. A repeat lumbar puncture continued to show a significant lymphocytic pleocytosis with moderately low sugar values.
