Pericardial tamponade caused by *Pasteurella multocida* infection after a cat bite

A K Al-Allaf, T C Harvey, A R Cunnington

Abstract

An unusual case of meningitis and pericardial tamponade caused by *Pasteurella multocida* after a cat bite is reported. The patient was successfully treated by antibiotics and pericardiocentesis and made an uneventful recovery from a life threatening condition. This case illustrates the potential dangers that can arise from a seemingly trivial and commonplace injury.

(Keywords: pasteurellosis; pericardial tamponade; cat bite)

Case report

A 62 year old woman was admitted with a 48 hour story of headache, neck stiffness, central pleuritic chest pain relieved by sitting forward and made worse by lying flat, fever, rigors, and drowsiness. Four days earlier she had been badly mauled by a stray cat and had sustained bites and lacerations to her right wrist.

On examination she was unwell, drowsy, dehydrated, and had a fever of 39.8°C. She had an obviously inflamed bite and scratch marks on her wrist with local cellulitis. Her blood pressure was 106/59 mm Hg, pulse 84/minute, regular and oxygen saturation was 96%. Heart sounds at this stage appeared normal with no murmurs or rub and chest examination was clear. There were no foci neurological signs but she was drowsy and confused and the provisional diagnosis was of meningoencephalitis and pericarditis due to septicemia or viraemia as a result of the injury.

Investigations

Her haemoglobin concentration was 132 g/l and white cell count 18.6 × 10⁹/l (90% neutrophils). Sodium concentration was 136 mmol/l, potassium 3.2 mmol/l, urea 10.1 mmol/l, creatinine 65 mmol/l, erythrocyte sedimentation rate 70 mm/hour, C reactive protein 316 mg/l, immunoglobulins and liver function tests were normal, and an autoimmune screen was negative. Chest radiography was normal. Electrocardiography showed diffuse ST segment elevation with upward concavity (fig 1); computed tomography of the skull was normal. Blood cultures grew Gram negative coccobacilli (later identified as *Pasteurella multocida*, sensitive to a variety of antibiotics including amoxicillin and cefotaxime). Lumbar puncture 72 hours after admission showed white cell count of 50 × 10⁶/l (100% neutrophils), a glucose of 4.2 mmol/l, and protein of 0.65 g/l. Culture was sterile (on antibiotics).

The patient was started on intravenous antibiotics (flucloxacillin and cefotaxime), rehydrated, and closely monitored. Over the first 72 hours her temperature settled but she developed atrial fibrillation and became progressively more confused and comatose with increasing hypoxia, hypotension, and diminished urine output, requiring ventilation and inotropic support. Swan-Ganz catheterisation revealed a low cardiac output with high filling pressures and increased peripheral vascular resistance. Echocardiography revealed a large pericardial effusion with early diastolic collapse of the right atrium suggestive of tamponade (fig 2).

Altogether 1150 ml of turbid fluid was aspirated by pericardiocentesis and a pericardial drain inserted. There was immediate haemodynamic improvement with a rise in systolic pressure from 85 to 220 mm Hg and the atrial fibrillation reverted to sinus rhythm during the procedure.

Her subsequent progress was uneventful. She regained consciousness and went on to make a good recovery over the next two weeks.

Discussion

Cardiac tamponade is a relatively uncommon sequela of a bacteraemia and may present with a wide spectrum of clinical features ranging from an asymptomatic elevation of intrapericardial pressure recognised during objective evaluation, to extreme haemodynamic com-
promise in the form of severe hypotension or electromechanical dissociation. If the fluid in the pericardium is not quickly removed, the patient will die from cardiogenic shock. The diagnosis is made from the clinical history, physical findings, and radiological and electrocardiographic suspicion and is easily confirmed by echocardiography.

Pasteurellosis, a zoonosis, is caused by a Gram negative coccobacilli found in the nasopharynx and gastrointestinal tract of many animals. About 50%–90% of domestic cats and dogs carry pasteurella species in their saliva and nasal tract and the organism is frequently found in injuries from cat scratches (75%) and dog bites (50%).

Pasteurella multocida may cause local wound infections in man as a result of contact with animals and serious systemic infection and sepsicaemia has been reported including endocarditis, pericarditis, polyarthropathy, and death. This case is believed to be the first reported instance of pasteurella pericardial tamponade.

The interesting aspect about this illness is that it was caused by a cat bite. This emphasises the importance of considering this unusual infection in all animal inflicted injuries.
