Clinical and pathological characteristics of Chinese patients with antineutrophil cytoplasmic autoantibody associated systemic vasculitides: a study of 426 patients from a single centre

M Chen, F Yu, Y Zhang, M H Zhao

Background: Antineutrophil cytoplasmic autoantibodies (ANCA) are serological markers of ANCA associated systemic vasculitides (AASV), which is one of the most common multisystem autoimmune diseases. Features of Chinese patients with AASV have not been fully investigated.

Objective: To analyse the clinical and pathological characteristics of Chinese patients with AASV.

Methods: 426 Chinese patients with AASV diagnosed in the past eight years were retrospectively studied and their clinical and pathological data were analysed.

Results: Of the 426 patients, 87 (20.4%) were Wegener’s granulomatosis, 337 (79.1%) were microscopic polyangiitis and two (0.5%) were Churg-Strauss syndrome. Only 201 of 426 (47.2%) patients were diagnosed within three months. Clinically, the patients had multisystem involvement. Altogether 371 of 426 (87.1%) had kidney involvement and 260 of 426 (61.0%) had lung involvement. The prevalences of renal involvement and fatigue were significantly higher in patients with MPO-ANCA than that in patients with PR3-ANCA; the prevalences of ophthalmic, nasal involvement, rash, and arthragia were significantly higher in patients with PR3-ANCA than those in patients with MPO-ANCA. The one and five year death rates were 13.1% and 22.4%, respectively. The percentage of patients progressing to end stage renal disease at one and five years was 15.9% and 27.1%, respectively.

Conclusions: AASV is not a rare autoimmune disease in Chinese people. Kidney and lung were the most vulnerable organs. For patients with multorgan damage, an ANCA test should be performed to make an early diagnosis and to start treatment in time.

VASCUITIS is an inflammatory process of blood vessels, histopathologically characterised by vessel wall destruction and occlusion of the vascular lumen. An attempt to classify the diverse forms of vasculitis resulted in the Chapel Hill international consensus definition, which used the vessel size as the determinant of classification. American College of Rheumatology (ACR) has proposed classification criteria for some of the diseases. Wegener’s granulomatosis (WG), microscopic polyangiitis (MPA), Churg-Strauss syndrome (CSS), and idiopathic rapidly progressive glomerulonephritis (iRPGN) are described as small vessel vasculitides and are acknowledged to be commonly associated with antineutrophil cytoplasmic autoantibodies (ANCA). They are termed as ANCA associated systemic vasculitides (AASV). Two fluorescence patterns of ANCA are distinguished by indirect immunofluorescence (IIF), the cytoplasmic staining pattern (cANCA), and the perinuclear staining pattern (pANCA). Most patients with a cANCA pattern obtained by IIF have ANCA directed against proteinase-3 (PR3), as determined by antigen specific ELISA. Patients with a pANCA mostly have ANCA directed against one of a variety of antigens, such as myeloperoxidase (MPO). The combination of a cANCA with PR3-ANCA and pANCA with MPO-ANCA are specific for WG, MPA, or iRPGN.

AASV must be recognised in time if successful treatment is to be implemented. Early diagnosis and appropriate immunosuppressive treatment are crucial for reducing the ability of acute vasculitis to cause death from major organ failure, for example, respiratory failure from pulmonary haemorrhage, and to reduce long term morbidity, for example, end stage renal failure.

AASV is one of the most common multisystem autoimmune diseases in the white population. A population based study from Norfolk, England, reported incidences of 8.5 cases per million for WG, 3.6 cases per million for MPA, and 2.4 cases per million for the CSS. In two large US cohorts studies of patients with WG, white people comprised more than 90% of all cases. Regional, geographical, ethnic, and seasonal differences in disease patterns and increasing incidence have been suggested, but lack confirmation. Studies from Norway suggested a doubling incidence of WG from 1992–1994 to 1995–1998. These figures probably reflect a real increase in incidence as well as improved awareness and diagnosis. AASV can occur at any age, especially elderly people.

The incidence of AASV in the Chinese population is unknown. In the early 1990s, after IIF-ANCA and ELISA using crude neutrophil acid extracts as solid phase ligands were established, a retrospective study of 50 hospitalised Chinese patients with crescentic glomerulonephritis or end stage renal disease showed that five of the 50 patients were ANCA positive. With the commercial IIF-ANCA kits being available and purified MPO and PR3 being used in routine ANCA screening assays, the prevalence of AASV increased substantially. In the past eight years, 426 patients with AASV were diagnosed in Peking University First Hospital. The clinical and pathological differences between ANCA associated systemic vasculitides and MPA, microscopic polyangiitis; CSS, Churg-Strauss syndrome; ACR, American College of Rheumatology; ANA, antinuclear antibodies; ESR, erythrocyte sedimentation rate; MMF, mycophenolate mofetil; MPO, myeloperoxidase.

Abbreviations: ANCA, antineutrophil cytoplasmic autoantibodies; AASV, ANCA associated systemic vasculitides; WG, Wegener’s granulomatosis; MPA, microscopic polyangiitis; CSS, Churg-Strauss syndrome; ACR, American College of Rheumatology; ANA, antinuclear antibodies; ESR, erythrocyte sedimentation rate; MMF, mycophenolate mofetil; MPO, myeloperoxidase.
prevalence of ANCA and the antigen specificities, as well as
demographic features of some of the Chinese patients with
AASV was investigated. It was suggested that AASV might
not be rare in the Chinese population. In this study, the
clinical and pathological manifestations of the Chinese
patients with AASV were investigated.

METHODS
Patients
A total of 426 patients with AASV, diagnosed from 1997 to
2004 in the Institute of Nephrology, Peking University First
Hospital, were enrolled into this retrospective study. All the
patients met the criteria of the Chapel Hill consensus
conference definition (for WG, MPA, or CSS) and ACR
classification criteria (for WG or CSS). Systemic lupus
erythematous, Henoch-Schölein purpura, rheumatoid
arthritis were excluded. Acute renal failure was defined by
the presence of progressively raised serum creatinine or 15% declined clearance rate of serum creatinine on the baseline
within days or weeks. Clinical data were collected and
analysed according to the organ involved.

IIF assay to detect ANCA
Standard IIF assay was performed according to the manu-
facturer (EUROIMMUN, Lübeck, Germany). Ethanol fixed
human polymorphonuclear leucocytes (PMN) were used to
detect ANCA and monkey liver sections were used to exclude
antinuclear antibodies (ANA). cANCA and pANCA were
distinguished according to staining patterns by two experi-
enced technicians.

Antigen specific ELISAs
Two highly purified known ANCA antigens, PR3 and MPO,
were used as solid phase ligands in ELISA, as previously
reported.9

Pathological examination
Renal pathological data of 122 cases were evaluated using
direct immunofluorescence, light and electron microscopy.
Specimens of kidney were required to have a minimum of 10
glomeruli for classification of glomerulonephritis with light
microscopy by the same renal pathologist.

Treatment protocols
Induction treatment included corticosteroids and cyclo-
phosphamide (CTX). Oral prednisone was prescribed at an initial
dose of 1 mg/kg/day for four to six weeks, with reducing
doses over time to 12.5 to 15 mg by three months. CTX
started on day 10–14 days after corticosteroids, daily oral
2 mg/kg/day or intravenous 0.7 g/m² every month. Patients
with acute renal failure or pulmonary haemorrhage received
three pulses of intravenous methylprednisolone (7–15 mg/kg/
day) before standard induction treatment. Some patients
with severe pulmonary haemorrhage received additionally
plasma exchanges. Azathioprine or mycophenolate mofetil
(MMF) was given in maintenance treatment.

Remission was defined as the absence of clinical signs or
symptoms or laboratory evidence of vasculitis activity. Relapse
was defined as the return of clinical signs or symptoms or
laboratory evidence of disease activity sufficient
to warrant a sustained increase in immunosuppressive
treatment.

RESULTS
Prevalence and demographic features
Of the 426 patients with AASV diagnosed from 1997 to 2004,
199 (46.7%) were male and 227 (53.3%) were female. Most of
the patients were from northern China. There was no
significant occupation of the patients. The average age was
56.1 (range 5–83) years old. Altogether 176 (41.3%) cases
were older than 65 years old and 38 (8.92%) cases were
younger than 20 years old. The number of diagnosed case
increased chronologically (fig 1). Eighty seven patients
(20.4%) were WG, 337 (79.1%) were MPA, and two (0.5%) were
CSS. Seventy (16.4%) of these patients were positive for
CANC A. Sixty nine of them could recognise PR3 only and the
rest one could recognise both PR3 and MPO in antigen
specific ELISA. Altogether 354 (83.1%) patients were positive
for pANCA with antigen specificity for MPO only in 346 (346
of 354, 97.7%) patients, and positive for both MPO and PR3
in eight cases (8 of 354, 2.3%). Two of 426 patients were
positive for both pANCA and cANCA. One of them could
recognise MPO only and the other could recognise both MPO
and PR3 (table 1).

Interval between onset of the disease and diagnosis
The mean and median time between onset of the disease and
testing for ANCA were 237.6 (ranging from 3 to 1460) and
60 days, respectively. Only 99 cases (23.2%) were diagnosed
within 30 days, 47.2% (201) cases within 90 days, 252 cases
(59.2%) within 180 days, 47 (11.0%) cases more than one
year, and one case was even diagnosed four years after the
onset of the disease. There was no significant difference of
the interval between onset of the disease and diagnosis
between patients with PR3-ANCA and MPO-ANCA.

Non-specific symptoms
Of the 426 cases, 260 (61.0%) had fatigue, 242 (56.8%) had
fever, 171 cases (40.1%) had significant weight loss, 84 cases
(30.8%) had arthralgia, 110 (25.8%) cases had muscle pain,
and 78 (18.3%) cases had a rash.

Renal manifestations
A total of 371 cases (371 of 426, 87.1%) had renal
involvement, of which 334 (90.0%) had haematuria, 314
(84.6%) had proteinuria, 307 (82.7%) had raised serum
creatinine with 229 (61.7%) diagnosed to have acute renal
failure, and only 31 cases (8.36%) had nephrotic syndrome.
Altogether 122 cases (32.9%) had a renal biopsy, of which 38
(31.1%) had focal segmental fibrinoid necrosis in glomeruli,
12 (9.84%) had fibrinoid necrosis in arterioles, 83 (68.0%)
reached the criteria of crescentic glomerulonephritis (over

![Figure 1](http://pmj.bmj.com)
50% glomeruli had large crescents formation), and 11 (9.02%) had granulomatous lesion in renal interstitium.

**Pulmonary manifestations**

Two hundred and sixty cases (260 of 426, 61.0%) had lung symptoms such as cough, often with sputum production, of which 104 (40.0%) had haemoptysis. One hundred and fifty cases had alveolar infiltrates or interstitial changes on chest films or computed tomography, of which 130 cases (86.7%) had shadows in one or both lungs and 79 (52.7%) had pulmonary interstitial fibrosis, multiple nodules, or cavitations.

**Manifestations of other organs**

Of the 426 patients, 83 cases (19.5%) had ophthalmic disease manifested as conjunctivitis, keratoconjunctivitis, episcleritis and uveitis, optical nerve vasculitis, and declining vision. Ninety nine cases (23.2%) had ear involvements, manifested as tinnitus, perforation of the tympanic membrane, and declining or loss of hearing. Thirty five cases (8.4%) had nasopharyngeal involvement, manifested as sinusitis, stuffiness, epistaxis, or even septal perforation. One hundred and eighty three cases (43.6%) had gastrointestinal involvement manifested as nausea, vomiting, anorexia, abdominal pain, loose bowels, or bloody faeces. Five patients had a gastrointestinal ulcer. Sixty seven cases (15.7%) had neurological disorders such as peripheral mononeuritis multiplex, dizziness, headache, and coma. Three patients had cerebral haemorrhage. One patient had Guillain-Barre syndrome (fig 2).

Further analysis showed that the prevalences of renal involvement and fatigue were significantly higher in patients with MPO-ANCA than that in patients with PR3-ANCA (90.2% vs 79.7%, \(\chi^2 = 6.21, p<0.05\); 63.7% vs 46.4%, \(\chi^2 = 7.24, p<0.05\), respectively); the prevalences of ophthalmic, nasal involvement, rash, and arthragia were significantly higher in patients with PR3-ANCA than those in patients with MPO-ANCA (31.9% vs 16.7%, \(\chi^2 = 8.53, p<0.01\); 21.7% vs 5.76%, \(\chi^2 = 19.1, p<0.01\); 27.5% vs 16.4%, \(\chi^2 = 4.76, p<0.05\); 43.5% vs 28.0%, \(\chi^2 = 6.54, p<0.05\), respectively) (table 2).

**Laboratory findings**

A total of 300 of 337 cases (89.0%) had anaemia, of which only 83 cases (27.7%) had mild anaemia with haemoglobin (Hb) over 90 g/l, 172 cases (57.3%) had moderate anaemia with Hb between 60 and 90 g/l, and 45 (15.0%) had severe anaemia with Hb less than 60 g/l. Altogether 125 of 287 (43.6%) cases had leucocytosis and 56 of 195 (28.7%) had thrombocytosis. A total of 265 of 285 cases (93.0%) had raised erythrocyte sedimentation rate (ESR), of which 92 (34.7%) were over 100 mm 1st h and 178 (67.2%) were over 60 mm 1st h. Altogether 132 of 185 cases (71.4%) had raised C reactive protein. No significant difference was found in these laboratory findings between PR3-ANCA and MPO-ANCA positive patients.

**Outcomes**

A total of 44 of 130 (33.8%) and 86 of 130 (66.2%) cases received prednisone together with daily oral or monthly intravenous CTX, respectively. After the induction phase treatment, 105 of 130 (88.5%) cases had complete or partial remission. One hundred and seven cases were followed up. The average duration of follow up was 29.7 (1–108) months. A total of 24 of 107 (22.4%) patients died and 29 of 107 (27.1%) patients progressed to end stage renal disease and received renal replacement treatment. The one and five year death rates were 13.1% and 22.4%, respectively. The percentage of patients progressing to end stage renal disease at one and five years was 15.9% and 27.1% respectively.

**DISCUSSION**

AASV is one of the most common multisystem autoimmune diseases in the white population. It is an important cause of mortality (if untreated) and morbidity (despite current aggressive treatment). The annual incidence and point prevalence of renal vasculitis in Europe is 10–20/million/year and 150–200/million, respectively.\(^1\) In China, after improved awareness and diagnostic techniques, more patients with AASV were diagnosed in recent years, but there is lack of systemic investigation on incidence. Over 400 patients with AASV were diagnosed in our centre in the past eight years and the number of patients increased chronologically. It was suggested that AASV was not rare in China.

In this study, it was found that the average age of Chinese patients with AASV was 56.1 (ranging from 5 to 83) years old. Over 40% of the cases were more than 65 years old, and nearly 1 of 10 of the cases were younger than 20 years old, showing that AASV could affect people of all age—elderly people were more susceptible, but children and teenagers were not rare. This is consistent with our previous studies and similar to the white population.\(^1\)\(^\text{14}\)

MPO and PR3 are the two important target antigens of ANCA for Chinese patients with AASV, which is consistent with the epidemiology reports in white populations.\(^2\)\(^\text{15}\) However, in our study, patients with MPA were about four times as many as patients with WG. Substantial evidences suggested that throughout Europe, there is a different proportion of WG and MPA. In northern Europe and Germany there are many more patients with WG than MPA, whereas in southern Europe, a study from Spain.
suggested that patients with MPA were about two to three times as many patients with WG. This may be attributed to the geographical, environmental, or genetic factors as there had been evidence that geographical and genetic factors both played a part in the pathogenesis of AASV. The preponderance of MPA might be one of the epidemiological characteristics of Chinese patients with AASV.

Kidney and lung are the two most vulnerable organs to be involved in patients with AASV. In this study, nearly 90% of cases had renal involvement and more than 60% of them had acute renal failure, which might be the major cause for long term end organ damage. However, the high prevalence of renal involvement might be to some extend a result of selective bias, because most patients with renal diseases were referred to us. Another possible reason might be the unawareness of the systemic disease by physicians and thus resulted in late diagnosis and increased prevalence of renal involvement. The prevalence of renal involvement and acute renal failure reported by the respiratory department in our hospital was 76.9% (10 of 13) and 38.5% (5 of 13), respectively. More than 60% had pulmonary involvement with 40% having pulmonary haemorrhage, which was the major cause of acute respiratory failure or death. Although 43% and 15.7% of the cases had gastrointestinal and nervous involvement respectively, they were often neglected by clinicians and these might be under-evaluated in this retrospective study. Besides visceral vasculitis, about 8% to 23% also suffered from auditory, ophthalmic, and nasal involvements. All the above mentioned findings showed that AASV is characterised by multisystem injury.

Although cANCA/PR3-ANCA was mainly found in patients with WG and pANCA/MPO-ANCA was mainly found in patients with MPA and iRPGN, it was not exclusive. Our study also found that there were some difference in the clinical manifestations between patients with PR3-ANCA and MPO-ANCA. The prevalences of fatigue and renal involvement were significantly higher in patients with MPO-ANCA than those in patients with PR3-ANCA. The prevalences of ophthalmic, nasal involvement, rash, and arthrigia were significantly higher in patients with PR3-ANCA than those in patients with MPO-ANCA. Some authors argued that one of the possible reasons for higher proportion of renal disease in patients with MPO-ANCA positive might be attributable to the delay of diagnosis. More patients with PR3-ANCA positive had upper respiratory and ophthalmic involvements, which probably reduce the patients’ and doctors’ delay. Earlier diagnosis and start of treatment might reduce the frequency of renal involvements. In this study, however, there is no significant difference of the intervals between onset of disease and diagnosis between PR3-ANCA and MPO-ANCA groups. Whether there are different mechanisms in the pathogenesis of renal disease in these ANCA subsets remains unclear.

Aberrant laboratory findings suggestive of active vasculitis included severe anaemia unparalleled with the degree of renal failure or pulmonary haemorrhage, or both, leucocytosis, thrombocytosis, increased non-specific inflammatory markers such as ESR and C reactive protein. The laboratory findings of our patients showed that most of them were in active phase at the time of diagnosis.

This study also preliminarily analysed the outcome of the patients. However, there were many patients lost during follow up, so the actual mortality and rate of end stage renal disease might be much higher.

The prognosis of untreated AASV is poor, with up to 90% of patients dying within two years. Early diagnosis is crucial, otherwise life threatening disease such as acute renal failure or respiratory failure may develop quickly. In this study, unfortunately, more than 40% of the patients were diagnosed six months after onset of the disease, and more than 10% of the cases were more than one year, which would undoubtedly worsen the prognosis. This showed that the awareness of this disease still needs to be improved in clinicians. Vassilopoulos reported that in patients with severe multi-organ dysfunction or pulmonary disorders, there was a high prevalence of ANCA. Therefore, for the suspected patients, prompt ANCA detection is crucial for the early diagnosis of AASV.

CONCLUSION

AASV is not rare in the Chinese population. Renal and pulmonary involvement was common and life threatening. For patients with multisystem involvement, ANCA testing using both IIF and antigen specific ELISA is recommended and it provides a helpful tool facilitating earlier diagnosis.

ACKNOWLEDGEMENTS

We are grateful to Dr Yanping Peng for assistance in collecting the data of the patients.
