Assessment of glycaemic control in stable type 2 black South African diabetics attending a peri-urban clinic

R T Erasmus, E Blanco Blanco, A B Okesina, Z Gqweta, T Matsha

Summary

Glycaemic control was assessed in type 2 black diabetics attending the diabetic clinic at a peri-urban hospital. Baseline glycosylated haemoglobin levels were measured and a subsequent estimation was carried out in those patients who attended a follow-up consultation to see whether current recommended targets for glycosylated haemoglobin levels were being attained. Out of 708 patients, mean age 56.3 years, 14.7% were insulin treated and 85.3% were non-insulin-treated. Target values of HbA1c < 7% were achieved in only 20.1% (142) of patients. Although mean glycosylated haemoglobin levels were significantly higher in females ($p=0.03$), the proportion of poorly controlled diabetics was similar in the two sexes. Patients whose HbA1c levels fell within the target values had diabetes of significantly shorter duration than those exhibiting poor control (5.0 ± 0.2 vs 7.03 ± 0.5 years). Obesity was present in 562 patients (79.4%). Target values were only achieved in 16.4% of non-obese and 21% of obese diabetics, with mean glycosylated haemoglobin levels being significantly higher ($p<0.05$) in the former group ($10.3\pm0.4\%$ vs $9.5\pm0.2\%$). Similar results were observed with respect to type of treatment, with only 14.4% of insulin-treated and 21% of non-insulin-treated diabetics achieving target values. The follow-up HbA1c estimation did not show any difference in the glycaemic control status of patients, with only 19.9% of them achieving the target values. Dietary advice (though minimal) seemed to have no impact on the metabolic control of our patients. These results suggest that glycaemic control was poor irrespective of sex, duration, BMI, educational status, dietary advice and type of treatment with recommended target values not being achieved in the majority of patients. Behavioural changes through health educational programmes need to be instituted with both patient and medical personnel being motivated to take this process forward.

Keywords: diabetes mellitus; black South Africans; glycaemic control

There is a growing body of evidence which suggests that the prevalence of diabetes mellitus in black South Africans has been steadily rising over the past two decades.¹ Several reports have stressed the high morbidity and mortality from diabetes among blacks from Africa as well as from America.^{2,3} Indeed, deaths attributable to diabetes are twice as high in blacks than white Americans in both sexes. A recent study from Tanzania showed that the prognosis for diabetic patients in tropical Africa, even where facilities for care exist, is also much worse than for patients in developed countries.⁴ Post-mortem studies have indicated that infection and acute metabolic complications were common causes of death.^{5,6} Whilst several studies have examined the cause and course of black diabetics admitted to hospital wards, little is known about the glycaemic control of stable black African diabetics attending the out-patient clinics.

It is recognised that adequate glycaemic control is important in preventing both the acute and long-term complications of diabetes mellitus⁷ and measurement of glycated haemoglobin is considered the gold standard method for assessing control status.⁸ The aim of the present study was to assess long-term glycaemic control in diabetic patients attending a black peri-urban community and examine some of the factors that may be associated with it, such as type of treatment, educational status, and dietary advice.

Methods

The research setting was the Umtata General Hospital, Umtata. This 1000-bed facility is the major referral centre for the former homeland of Transkei. The diabetic clinic is held once a week and all patients (Xhosa speaking) from the peripheral clinics, as well as within the hospital, are referred to it. Patients are usually seen at 3-monthly intervals and medical care is essentially free (including drugs) except for a small fee of six Rands (70 p) at each clinic visit. The study comprised 708 consecutive adult black type 2 diabetics attending the clinic over a one-year period. The case notes were reviewed and the data extracted included demographic data (sex, age, educational level), medical history (age at onset, duration of disease, family history), anthropometric data (weight, height), type of treatment, and related laboratory test results (fasting blood sugar, lipids).

Accepted 3 June 1999

The present study consisted of a cross-sectional observational analysis of metabolic control in 708 diabetic patients in which long-term glycaemic control was assessed by a baseline determination of glycosylated haemoglobin (HbA1c); and an observational cohort study using a second estimation of HbA1c carried out in 281 patients who attended a follow-up consultation within a period of 3 to 12 months.

Glycaemic control was classified according to the HbA1c level as 'acceptable' (<7%) or 'poor' (>7%) in accordance with the target values recommended by the British Diabetic Association.⁹ Body mass index (BMI) was calculated using the Quetelet's index (kg per metre squared) and the cut off points used for diagnosis of obesity were 25 for females and 27 for males. HbA1c assays were performed using the IMx Glycated Haemoglobin assay package (Abbot, USA). This method is based on ion capture using a boronate affinity binding complex (normal range 4.4–6.4%).

EDUCATIONAL STATUS

Patients were categorised into two main groups on the basis of education received (up to standard 7 or standard 8 and above). As the number of patients with tertiary education was relatively small, they were combined with those that had received secondary education.

DIABETES EDUCATION

Since the diabetic clinic did not operate a formal diabetes counselling programme at the time of this study, patients were only asked if they had received individually any form of dietary advice from the physician.

STATISTICAL ANALYSIS

Data were entered in a data base file using the dBase III program and further analysed using the EPI6 program to obtain and compare mean values of variables. Frequencies were expressed as percentages and means $\pm$ SEM. Chi-square analysis was used to compare frequencies. Analysis of variance was used for continuous variables. The correlations between glycated haemoglobin levels and other intervening variables were tested using regression analysis. Statistical significance was accepted at $p < 0.05$.

Results

PATIENTS

There were 708 type 2 diabetics of mean age 56.3 ± 0.44 years; 513 were females (72.5%) and 195 males (27.5%). The duration of diabetes ranged from 0 to 36 years with a mean of 6.9 ± 0.3 years. The majority (604, 85.3%) were non-insulin-treated and 104 (14.7%) were insulin-treated, both groups being similar with respect to mean age and sex (table 1). In total, 281 patients were followed up, 217 (77.2%) females and 64 (22.8%) males, with similar characteristics to the whole sample (mean age 56.0 ± 0.7 years, mean duration 7.4 ± 0.34 years, 18.5% insulin-treated and 81.5% non-insulin-treated).

Table 1 Overall clinical characteristics of patients

	Male	Female	Total
<i>n</i>	195	513	708
Age (years)	55.4 ± 0.9	56.6 ± 0.5	56.3 ± 0.4
Duration (years)	7.0 ± 0.5	6.8 ± 0.3	6.9 ± 0.3
Mean HbA1c (%)	9.3 ± 0.2	9.8 ± 0.1	9.6 ± 0.1
BMI	28.4 ± 0.4	$35.2 \pm 0.3^*$	31.2 ± 0.3
Prevalence of obesity (%)	59.0	87.1*	79.9
Insulin-treated	37	67*	104
Non-insulin-treated	158	446*	604

* $p < 0.05$

Table 2 Frequency distribution of glycosylated haemoglobin values

HbA1c (%)	Male	Female	Total (%)
<7	43	99	142 (20.1)
7.1–8.9	55	118	173 (24.4)
9.0–10.9	44	141	185 (26.1)
11.0–12.9	35	91	126 (17.8)
>12.9	18	64	82 (11.6)

GLYCAEMIC CONTROL

At the beginning of the study the overall mean HbA1c was $9.6 \pm 0.1\%$. Target values of HbA1c < 7% were achieved in only 20.1% of patients; 358 patients (50.5%) had values between 7.1% and 10.9%, while 208 patients (29.4%) had values over 11% (table 2). Although mean glycosylated haemoglobin levels were significantly higher in female than male diabetics, the occurrence of poor glycaemic control was similar in the two sexes (80.7% and 77.9%, respectively) (table 1).

OBESITY

The overall occurrence of obesity in our study was 79.4% with a higher prevalence amongst females ($p < 0.05$). Both obese and non-obese patients exhibited poor metabolic control with higher mean glycosylated haemoglobin levels in the latter (table 3).

TYPE OF TREATMENT

Glycaemic control was similar in insulin-treated and non-insulin-treated patients; 14.4% in the former and 21% in the latter group achieved target values for HbA1c.

DURATION OF DIABETES

Patients with longer duration of diabetes exhibited poorer glycaemic control, and diabetics of more than 7 years duration had almost a two-fold increase in the occurrence of poor glycaemic control (Odds Ratio=1.72).

Table 3 Relationship of glycaemic control to sex, type of treatment, and obesity

Type of treatment	Freq of obesity (%)	Obese HbA1c (%)	Non-obese HbA1c (%)
Insulin-treated	76.9	9.6 ± 0.4	10.7 ± 0.7
Non-insulin-treated	79.8	9.4 ± 0.1	10.3 ± 0.3
Total	79.4	9.6 ± 0.1	10.3 ± 0.3

Table 4 Glycaemic control in follow-up patients; the difference between glycaemic control categories was $p < 0.05$ at both stages

Stage of study	Glycaemic control	n	Freq (%)	Mean HbA1c (%)	Mean duration (years)
Beginning	good	53	18.9	6.1 ± 0.1	5.3 ± 0.7
	poor	228	81.1	10.5 ± 0.2	7.8 ± 0.4
Follow-up	good	56	19.9	7.0 ± 0.3	5.7 ± 0.8
	poor	225	80.1	9.9 ± 0.2	7.8 ± 0.4

EDUCATION

The educational status of 70.6% of patients was less than standard 8. However, similarly poor glycaemic control was observed in both groups.

Although 561 patients (79.2%) received some form of dietary advice, the majority of these (80.7%) did not attain recommended target values for HbA1c. A similar pattern was observed in patients who did not receive any dietary advice, with 76.7% not achieving the target values.

COHORT GLYCAEMIC CONTROL ANALYSIS

The comparison of the initial glycated haemoglobin level with a subsequent follow-up estimation performed in the 281 cases for whom such data were available, did not show any significant change with respect to glycaemic control status (table 4).

Discussion

Whilst morbidity and mortality data in black African diabetics are limited, there are reports that the course of the disease is much more severe in black than white diabetics. For example, various studies from America have highlighted poor glycaemic control in black diabetics.³ This observation has also been made in diabetics from black Africa² and other third-world countries.¹⁰

The results of this study showed that glycaemic control was poor in the majority of patients, irrespective of sex, treatment, or duration of diabetes. Our findings agree with the results of Weatherspoon¹¹ and are also supported by some race-based studies which found not only a poorer glycaemic control in blacks but also reported that black women in particular had high HbA1c levels.^{12, 13} The poor metabolic control found at the beginning of

study and even after attendance at the diabetic clinic may reflect insufficient motivation, lack of knowledge, incorrect beliefs about diabetes, and particular cultural values, all of which are recognised to be potential barriers to improving diabetic care for blacks.¹⁴

Non-obese black diabetics from other parts of Africa have been reported to have poor glycaemic control but this has generally been attributed to pancreatic disease, as many such patients have extremely low BMI.¹⁵ It is unlikely that this was the case in our patients as the majority of the non-obese diabetics were neither thin nor were there clinical signs suggestive of pancreatic disease.

An interesting observation was that glycaemic control was completely independent of the educational level of our patients. Although the majority of patients had received some form of dietary advice, it was not assessed or regularly reinforced. It is possible that the lack of a regular and intensive diabetes education programme, due to the lack of health and nursing personnel in our facility, contributed to the poor metabolic control status even in those with better educational status.¹⁶ Dietary advice has been reported to improve serum lipid levels and reduce related long-term complications but not necessarily improve glycaemic control. D'Eramo-Melkus and colleagues¹⁷ found dietary advice to be helpful in improving metabolic control only when intense individual counselling leads to behavioural changes resulting in and promoting weight loss.

Our data imply that, even among clinic patients selected on variables that may be biased towards good adherence, target values were difficult to achieve. It is clear that urgent intervention strategies need to be designed and implemented to reduce the long-term complications of diabetes, especially at a time when healthcare costs are becoming prohibitively high. Behavioural changes through health educational programmes need to be instituted. Both patient and medical personnel need to be motivated to take this process forward. The UKPDS^{18, 19} has reported the beneficial effects of metformin in the metabolic control of overweight diabetics and emphasised the need for strict control of blood pressure. This message needs to be reinforced and implemented in the management of our patients and could be useful in improving their metabolic control.

Medical Anniversary

Sir Patrick Manson, 3 October 1844

(Sir) Patrick Manson (1844–1922) was born at Cromlet Hill, Aberdeenshire, the second son of a bank manager and laird. He was educated at Aberdeen University and became MD (1865) for a thesis on the internal carotid artery. He became a physician in Formosa and then Hong Kong. He added to scientific knowledge on filariasis due to *Schistosoma mansoni*, malaria, lung fluke and *Diphyllbothrium mansoni* (dog and cat worm). In later life he practised in Queen Anne Street, London, and gave tropical medicine lectures in several London hospitals. He earned the title, Father of tropical medicine, when he founded the London School of Tropical Medicine. He died on 9 April 1922 in County Galway. — *DG James*
