COLITIS

THE COMBINED OPAQUE ENEMA USING OPAQUE FLUIDS OTHER THAN BARIUM

DIVERTICULOSIS AND DIVERTICULITIS

Illustrations

- FIG.
1. Without preparation and apparent hold up in the hepatic portion of the transverse colon.
 2. After thorough preparation, normal bowel, same colon.
 - 3a. Example of incompletely or carelessly administered opaque enema.
 - b. The same case with enema correctly administered.
 4. Anatomical limits.
 5. Megacolon with small carcinoma showing at the recto-sigmoidal junction.
 6. Shows the greatly dilated colon from the splenic flexure to the rectum, while the area of the transverse colon seen filled shows normal calibre.
 7. Same colon after administration of spinal anaesthesia and St. Mark's anti-incontinence catheter in rectum holding the enema.
 8. Cavernous angioma.
 9. Carcinoma of the pelvo-rectal junction with stenosis.
 10. Very early carcinoma of the sigmoid flexure showing only groove filling defect along the right side, with insert local of the right oblique view.
 - 11a. Apparently normal barium enema.
 - 11b. Oblique view showing stenosed area.
 - 11c. Contact view of stenosed area, showing some thickening.
 12. Opaque enema. Final stage fibrosing diverticulitis with stenosis and stricture.
Insert.—Post-operative specimen showing a fibrosing stricture, and below, an early carcinoma.
 13. Filling defect of iliac colon and insert after compression. The appearance suggested diverticulosis, but at operation proved to be malignant.
 - 14a. Opaque enema *intra muros*, showing no tumour.
 - b. Right oblique.
 - c. Compression view showing carcinoma.
 15. Double carcinoma of colon not shown by opaque enema.
 16. Bowel over-filled with the opaque enema masking carcinoma of the Hepatic Flexure.
 17. Same as Fig. 18 properly filled and carcinoma now demonstrated.
 - 18a. Filling defect due to polypus and, insert, specimen after operation.
 - b. Polyp of transverse colon.
 19. Filled defect of lipoma with insert of local area.
 20. Intussusception of the transverse colon.
 21. Opaque meal radiograph showing spasm of transverse colon and wrongly reported as carcinoma.
 22. Spontaneous local gas production splenic flexure area.
 23. Evacuation radiograph. Local gas showing clearly small carcinoma splenic flexure area.
 24. Excised specimen showing small carcinoma.
 25. Shows first opaque enema.
 26. Shows second opaque enema after 40 oz. of urine have been removed.
 27. { Showing instruments used with St. Mark's anti
 28. { incontinence device.
 29. {
 30. a, b and c. Evacuation radiograph of case of polyposis.
 31. a and b. Multiple polypi shown by Reduction Density technique but not demonstrated by ordinary opaque enema.
 32. Ulcerative colitis with areas of stenosis.
 33. Tuberculous colitis. Insert showing foci in the lungs.
 34. The syphilitic colon. Insert of chest showing aortitis.
 35. The growth of carcinoma over a period of three years.
 36. a, b, c, d. Early diverticulosis recorded over a period of three years.
 - 37a. Case showing 5th stage diverticulosis of the iliac and pelvic colons in 1937.
 - b. Same patient now examined six years later and in the area of the diverticulosis now a carcinoma present.
 38. A 5th stage diverticulosis of the iliac colon with a carcinoma in the centre of the diverticulosis.
 39. Composite diagram of the five stages of diverticulosis.
 - 40a. "Ripple Border" effect, seen in case examined in 1933.
 - b. Same case in 1943, now 5th stage diverticulosis.
 - c. 2nd stage diverticulosis, "Palisading stage".
 - d. 4th stage diverticulosis retractable ballooning.
 - e. 5th stage diverticulosis—"Permanent diverticula".
 41. Fibrosing Diverticulitis under pressure with air inflation but no relaxation of the colon walls.
