The exact relationship between ulcerative colitis and auto-immune haemolytic anaemia in these two cases is not known and it is possible that it is fortuitous. However, since there is evidence that both diseases have an immunological basis, it would seem likely that the cause of the two conditions is in some way linked. In any event, it is important to consider haemolysis as a cause of anaemia in ulcerative colitis.

Gastric carcinoma and Turner’s syndrome

Summary
The case is described of a gastric carcinoma developing in a 34-year-old female with Turner’s syndrome. The association has not been previously reported. The literature on the appearance of malignant disease in disorders of the sex chromosomes is reviewed.

History
An unmarried 34-year-old female was first seen in February 1973, with a 3-week history of dull epigastric pain relieved by food, vomiting but no haematemesis, weakness, effort dyspnoea and thirst and polyuria. She had never had a menstrual period. On examination she was obviously anaemic and had many external stigmata of Turner’s syndrome, including short stature (146.6 cm), scanty pubic and axillary hair, numerous pigmented naevi, undeveloped breasts, a low hair-line at the back of the neck, and was mentally subnormal. There was a soft apical pansystolic murmur. Routine urine testing revealed 2% glycosuria.

Investigations
Haemoglobin 6.7 g/100 ml; MCHC 28; WBC 7000/mm³; platelet count normal; serum and red cell folate, serum B12, urea and electrolytes, liver function tests, protein-bound iodine, total proteins and electrophoretic strip and chest X-ray were all normal; a buccal smear showed the typical chromosome count of Turner’s syndrome (45XO).

Barium meal and swallow were normal; an IVP revealed bilateral duplex pelvi-calyceal and ureteric systems; a skeletal survey was normal except for unfused iliac epiphyses and spina bifida occulta of S1 and S2; gastroscopy and sigmoidoscopy were normal; a glucose tolerance curve was of diabetic type; serum iron was reduced to 55 μg/100 ml with a TIBC of 480 μg/100 ml.

A diagnosis of iron deficiency anaemia of undetermined aetiology was made.

Treatment
She was treated with oral ferrous sulphate with a resultant 20% reticulocytosis and a return of haemoglobin concentration to normal. Her diabetes mellitus was controlled on oral tolbutamide.

Progress
She remained well until July 1973 when she was re-admitted to hospital because her haemoglobin had fallen to 4.9 g/100 ml. She received blood transfusion and oral ferrous sulphate and remained well until November 1973 when she was re-admitted with vomiting and anaemia of 7.2 g/100 ml. At gastroscopy (Mr R. M. Kirk) a rigid non-peristaltic mass was seen in the pre-pyloric region and at laparotomy, a pyloric carcinoma with extensive hepatic and peritoneal metastases was found. Gastro-jejunostomy was performed. Histology revealed an undifferentiated mucus-secreting adenocarcinoma with metastases to the draining lymph nodes.

Discussion
This patient demonstrates a number of known associations of Turner’s syndrome including duplication of the urinary collecting system (Grumbach, 1971) and diabetes mellitus (Jackson et al., 1966). It is of interest that diabetes mellitus is also a recognized association of another abnormality of sex
Secondary syphilis presenting with jaundice

Summary
A patient with secondary syphilis presenting with jaundice is reported. Hepatic histology showed evidence of non-specific granuloma and active hepatitis but no cholestasis. This has been treated successfully with antisypilicit therapy. The possibility of syphilitic pancreatitis and diabetes mellitus is discussed. The importance of serological tests for syphilis in jaundice of obscure origin is emphasized.

Introduction
The secondary stage of syphilis has always been a diagnostic problem because of protean manifestations. Syphilitic hepatitis is rare and has received scanty attention in the literature. Few histological studies have been reported (Parker, 1972). Hahn (1943) in a review of the literature could find only eighty cases of hepatitis among 33,825 patients with early syphilis, though in none was the association between the liver disease and the syphilis clearly demonstrated (Baker et al., 1971). Lee, Thornton and Conn (1971) mentioned that they were able to collect only six more patients with early syphilitic hepatitis since 1943. We describe here the case of a patient with secondary syphilis who presented with diabetes mellitus, maculopapular cutaneous rash and jaundice emphasizing the bizarre behaviour of the illness.

Case report
A 56-year-old white male patient was admitted in March 1973, complaining of tiredness, thirst and...
