Sepsis, septicemia, sepsis syndrome, and septic shock: the correct definition and use

Sepsis is an old medical term which comes from the Greek 'sepsin' meaning 'to make putrid'. Although most authors agree that sepsis refers to the systemic response to infection caused by any class of microorganisms, a single comprehensive and correct definition of this widely used term is still lacking. Also, in some medical dictionaries sepsis is defined incorrectly. For example, *Stedman's Medical Dictionary* defines this term as the presence of various pus-forming and other pathogenic organisms, or their toxins, in the blood or tissues. This definition does not reflect the presence of illness in the host, and thus it is a more suitable definition of bacteraemia, viraemia, endotoxaemia, etc, where the presence of these microorganisms or their toxins in the bloodstream does not always necessitate the occurrence of illness. So, sepsis should be defined as the systemic inflammatory response to infection caused by any class of microorganisms with the invasion of these microorganisms or their toxins in the bloodstream causing illness. This illness is clinically manifested by fever or hypothermia, tachycardia, and tachypnea, and it may be associated with various degrees of injury to one or more major organs. Thus, sepsis may be graded as mild, moderate, or severe, according to the severity of the associated organ or organs, injury and failure. When sepsis causes shock, this situation is defined as septic shock, and there is a consensus regarding this definition.

Some authors have recently begun to use the terms 'septic syndrome' and 'systemic inflammatory response syndrome' to describe the presence of severe sepsis or septic shock. I believe that the introduction of these terms is unnecessary since the term sepsis with its degrees (mild, moderate, and severe), and septic shock, as defined above are comprehensive and more correct and clear.

The term 'septicemia' is frequently used in the medical literature and still appears in most medical journals, and in recent editions of medical textbooks, and of medical dictionaries. Septicaemia is defined as a systemic disease caused by the spread of microorganisms and their toxins via the circulating blood. However, the term sepsis, as defined above, describes more clearly this situation, thus the term 'septicemia' is unnecessary. Furthermore, the suffix 'emia' means blood, and when it is connected with another word it means that something is present in the circulating blood, eg, bacteraemia when bacteria are present in the bloodstream. Thus, the term 'septicemia' means that sepsis is present in the circulating blood. However, as sepsis refers to the systemic response to infection caused by any class of microorganisms or their toxins, and not a particle which can circulate in the bloodstream, the term 'septicemia' is meaningless, confusing, and unsuitable. Thus, I suggest that the term 'septicemia' is no longer used in the medical literature.

In summary, the appropriate terms to use to describe an infection by any microorganism when the microorganism or its toxin is present in the bloodstream are bacteraemia, viroaemia, fungaemia, endotoxaemia, etc. When the invasion of these microorganisms or their toxins into the bloodstream causes illness, this may be defined as mild, moderate, or severe sepsis, or septic shock, whichever is appropriate.
